

# **Laboratory Certificate**

This is to certify that Smt./Sri	KOUSHIK G	Reg No <u>20201ISE00</u> 24
has satisfactorily completed the	e course of Experime	ents in <u>DATA HANDLING</u>
AND VISUALIZATION Prescrib	ed by the PRESIDE	NCY UNIVERSITY in the
Laboratory of this College in the	e year <u>2023 - 2024</u>	
	Signature	of the Lecturer
DATE:	in	Charge

# INDEX

SI NO.	Name of the Experiment
01	Introduction to Numpy
02	Working to Pandas
03	Data Cleaning
04	Zscore Normalization
05	Outlier Detection with IQR
06	Matplotlib
07	Interacting with Web API
08	Colormaps
09	Heatmaps
10	Seaborn color pallette
11	Univariate, Bivariate, Multivariate Visualization
12	Text
13	Time Series

#### LABSHEET 1

```
from matplotlib import pyplot as plt
plt.style.use('seaborn-whitegrid')

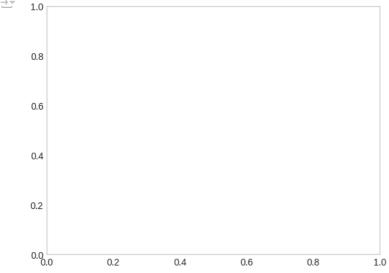

import numpy as np
print("step 1")

step 1

DATA FRAME
```

```
import pandas as pd
data = {'Name':['Alice', 'Bob', 'Claire', 'David'],
        'Age':[20, 21, 20, 22]}
df = pd.DataFrame(data)
print(df)
           Name Age
        Alice 20
                   21
           Bob
      2 Claire
                   20
      3 David 22
# creating a dataframe from a list of dictionary
data = [{'Name': 'Alice', 'Age': 20},

{'Name': 'Bob', 'Age': 21},
        {'Name': 'Claire', 'Age': 20},
{'Name': 'David', 'Age': 22}]
df = pd.DataFrame(data)
print(df)
           Name Age
         Alice
           Bob
                  21
      2 Claire
                   20
         David 22
```

#### pd.DataFrame(df)

Start coding or generate with AI.

## LABSHEET 3

# Data Cleaning and Data Preprocessing:

- 1. Data cleaning is the process of changing or eliminating garbage, incorrect, duplicate, corrupted, or incomplete data in a dataset.
- 2. There's no such absolute way to describe the precise steps in the data cleaning processbecause the processes may vary from dataset to dataset.

□ Data Cleaning Cycle

#### Missing Values:

```
# import the pandas library
import pandas as pd
import numpy as np
df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
'h'],columns=['one', 'two', 'three'])
print(df)
# df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
# print (df)
\rightarrow
                        two
                                 three
              one
     a 0.375319 -0.763927 -0.762393
     c -1.093644 1.335944 -0.668966
     e -0.013401 0.155461 -0.843651
     f 0.423813 0.900266 -0.828664
     h -0.644593 2.654895 1.211697
```

#### **Check for Missing Values:**

To make detecting missing values easier (and across different array dtypes), Pandas provides the **isnull**() and **notnull**() functions, which are also methods on Series and DataFrame objects –

```
5/15/24, 3:25 PM
                                       DataCleaning20201ISE0024.ipynb - Colab
   import pandas as pd
   import numpy as np
   df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f',
   'h'],columns=['one', 'two', 'three'])
   df = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
   # print (df['one'].isnull())
   # print(df)
   print(df["one"].isnull())
              False
         h
              True
              False
         C
         d
               True
         е
              False
         f
              False
               True
         g
              False
         h
         Name: one, dtype: bool
```

#### **Replacing the Missing Values**

```
#Replace the missing values by 0
import pandas as pd
import numpy as np
df = pd.DataFrame(np.random.randn(3, 3), index=['a', 'c', 'e'],columns=['one',
'two', 'three'])
df = df.reindex(['a', 'b', 'c'])
print (df)
print ("NaN replaced with '0':")
print (df.fillna(0))
\rightarrow
                                three
             one
                        two
     a -0.961858 -1.671248 0.556286
             NaN
                        NaN
                                   NaN
     c -0.386504 -0.709324 0.622838
     NaN replaced with '0':
             one
                                three
                        two
     a -0.961858 -1.671248 0.556286
     b 0.000000 0.000000 0.000000
     c -0.386504 -0.709324 0.622838
```

#### Fill NA Forward and Backward

```
# Method Action
pad/fill Fill methods Forward
bfill/backfill Fill methods Backward
```

```
DataCleaning20201ISE0024.ipynb - Colab

                 NaN
                            NaN
        e -0.991040 -0.749165 0.259387
         f -1.300768 -0.000567 -0.056870
                 NaN
                            NaN
         g
         h 0.497341 0.984014 -1.094049
                 one
                            two
                                     three
         a -0.481989 -1.249458 -2.316982
         c 1.119240 -1.054186 -0.972090
         e -0.991040 -0.749165 0.259387
         f -1.300768 -0.000567 -0.056870
```

#### Replace Missing (or) Generic Values:

We can achieve this by applying the **replace** method.

h 0.497341 0.984014 -1.094049

Replacing NA with a scalar value is equivalent behavior of the **fillna()** function.

```
import pandas as pd
import numpy as np
df = pd.DataFrame({'one':[10,20,30,40,50,2000],
'two':[1000,0,30,40,50,60]})
print(df)
print (df.replace({1000:10,2000:60}))
\rightarrow
          one
                 two
     0
           10
                1000
     1
           20
                   0
     2
           30
                  30
     3
           40
                  40
     4
           50
                  50
     5 2000
                  60
         one two
     0
          10
                10
     1
          20
```

0

50 50 5 60 60

## □ Data Preprocessing

- 1. Load data in Pandas
- 2. Drop columns that aren't useful
- 3. Drop rows with missing values
- 4. Create dummy variables
- 5. Take care of missing data
- 6. Convert the data frame to NumPy

#### Download Titanic-Dataset from Kaggle.com.

Here we are going to use train.csv dataset for preprocessing.

```
import pandas as pd
import numpy as np
from google.colab import drive
drive.mount('/content/drive')
```

Mounted at /content/drive

df = pd.read\_csv(r"C:\Users\Thejas Venugopal\Downloads\train (1).csv") df.info()

#### **Creating Dummy variables**

Instead of wasting our data, let's convert the Pclass, Sex and Embarked to columns in Pandasand drop them after conversion.

float64

- Colab

```
dummies = []
cols = ['Pclass', 'Sex', 'Embarked']
for col in cols:
  dummies.append(pd.get_dummies(df[col]))
```

Transfor the eigth columns

```
titanic_dummies = pd.concat(dummies, axis=1)
```

Concatenate the values with data frame

```
df = pd.concat((df,titanic_dummies), axis=1)
```

Remove the unwanted cols

```
df = df.drop(['Pclass', 'Sex', 'Embarked'], axis=1)
```

#### Take care of Missing data

Let's compute a median or interpolate() all the ages and fill those missing age values. Pandashas an interpolate() function that will replace all the missing NaNs to interpolated values.

## Min Max Scaler and Standardization

**Normalization** is a rescaling of the data from the original range so that all values are within thenew range of 0 and 1.

A value is normalized as follows: y

```
= (x - min) / (max - min)

from sklearn.preprocessing import MinMaxScaler data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]] scaler = MinMaxScaler() print(scaler.fit(data))

MinMaxScaler() print(scaler.data_max_) print(scaler.transform(data))

→ MinMaxScaler() [ 1. 18.] [[0. 0. ] [0.25 0.25] [0.5 0.5 ] [1. 1. ]]
```

# □ Data Standardization

**Standardizing** a dataset involves rescaling the distribution of values so that the mean of observed values is 0 and the standard deviation is 1.

A value is standardized as follows:

```
y = (x - mean) / standard_deviation
```

Where the mean is calculated as:

```
mean = sum(x) / count(x)
```

And the standard\_deviation is calculated as: standard\_deviation

```
= sqrt( sum( (x - mean)^2 ) / count(x))
```

```
from numpy import asarray
from sklearn.preprocessing import StandardScaler
# define data
data = asarray([[100, 0.001],
    [8, 0.05],
    [50, 0.005],
    [88, 0.07],
    [4, 0.1]])
print(data)
# define standard scaler
scaler = StandardScaler()
```

## ☐ LABSHEET 10

## □ Seaborn Color Palettes

Color is an utmost important aspect of figure styling because it reveals pattern in the data if used effectively; or hide those patterns if used poorly. Even professionals often assume usage ofcolor to portray data as a solved problem. They just pick a palette from a drop-down menu (probably either a grayscale ramp or a rainbow), set start and end points & finally press apply. But it isn't that simple and thus many visualizations fail to represent the underlying data as appropriately as they could.

Primary objective with choice of color is to illuminate datapoints that are concealed in hugedatasets. Quoting Robert Simmon:

Although the basics are straightforward, a number of issue complicate color choices in visualization. Among them: The relationship between the light we seeand the colors we perceive is extremely complicated. There are multiple types ofdata, each suited to a different color scheme. A significant number of people (mostly men), are color blind. Arbitrary color choices can be confusing for viewers unfamiliar with a data set. Light colors on a dark field are perceived differently than dark colors on a bright field, which can complicate some visualization tasks, such as target detection.

One of the most fundamental and important aspects of color selection is the mapping of numbers to colors. This mapping allows us to pseudocolor an image or object based on varying numerical data. By far, the most common color map used in scientific visualization is the rainbow color map. Research paper on **Diverging Color Maps for Scientific Visualization** by

Kenneth Moreland very well deals with the extended color concepts, if the topic interests you forfurther analysis.

With all that been said, let us now focus on what Seaborn has to offer BUT before doing that let me once again remind you that Seaborn runs on top of Matplotlib so any color that is supported by Matplotlib will be supported by Seaborn as well. So at first, let us understand what Matplotlibhas to offer:

5/15/24, 3:52 PM - Colab

SeabornColor20201ISE0024.ipynb an RGB or RGBA tuple of float values in [0, 1] (e.g., (0.1, 0.2, 0.5) or (0.1, 0.2, 0.5, 0.3))a

- hex RGB or RGBA string (e.g., '#0F0F0F' or '#0F0F0F0F')
- a string representation of a float value in [0, 1] inclusive for gray level (e.g., '0.5') one of
- \* {'b', 'g', 'r', 'c', 'm', 'y', 'k', 'w'}
- a X11/CSS4 color name
- a name from the xkcd color survey prefixed with 'xkcd:' (e.g., 'xkcd:sky blue') one of
- {'C0', 'C1', 'C2', 'C3', 'C4', 'C5', 'C6', 'C7', 'C8', 'C9'}
- one of {'tab:blue', 'tab:orange', 'tab:green', 'tab:red', 'tab:purple', 'tab:brown', 'tab:pink', 'tab:gray', 'tab:olive', 'tab:cyan'} which are the **Tableau** Colors from the 'T10' categorical palette (which is the default color cycle).

Note that all string specifications of color, other than "CN", are NOT case-sensitive. Let us brieflygo through a couple of common supported colors here:

- RGB/RGBA tuples are 4-tuples where the respective tuple components represent Red, Green, Blue, and Alpha (opacity) values for a color. Each value is a floating point number between 0.0 and 1.0. For example, the tuple (1, 0, 0, 1) represents an opaque red, while (0, 1, 0, 0.5) represents a half transparent green.
- This is actually another way of representing RGBA codes and common Color Conversion
   Calculators can be used to translate values. Here is a <u>Hex to RGBA</u> and <u>RGB to Hex</u> Color
   converter for your future assistance.
- Dictionary of values from {'C0', 'C1', 'C2', 'C3', 'C4', 'C5', 'C6', 'C7', 'C8', 'C9'} represent **Color Quantization**. I have attached a link in the provided notebook that shall guide you to anonline book where on Page-29 you could find specifics.

My sole purpose of keeping you posted of Matplotlib background every now and then is only to ensure that when you get to production-level and try to customize a plot as per your analysis, youshould know what is ACTUALLY running in the background. This shall empower you to accordingly tweak parameters here and there. Let us now look into few Seaborn options for colors:

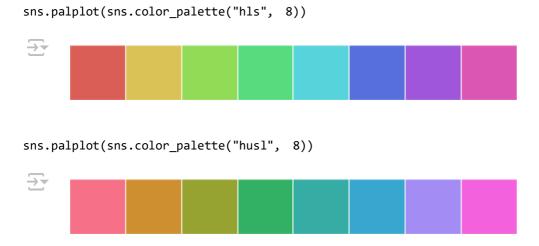

```
# Importing required Libraries:
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
%matplotlib inline

# Setting a figure size for all the plots we shall be drawing in this kernel:
sns.set(rc={"figure.figsize": (6, 6)})
Building color palettes:
```

The most important function for working with discrete color palettes is **color\_palette()**. This function provides an interface to many (though not all) of the possible ways you can generate colors in seaborn, and it's used internally by any function that has a **palette** argument (and in some cases for a **color** argument when multiple colors are needed).

color\_palette() will accept the name of any seaborn palette or matplotlib colormap (exceptjet,
which you should never use). It can also take a list of colors specified in any valid matplotlib format
(RGB tuples, hex color codes, or HTML color names). The return value is always a list of RGB tuples.

Finally, calling color\_palette() with no arguments will return the current default color cycle.

Let me explain these Qualitative (or categorical) palettes. These are best when you want to distinguish discrete chunks of data that do not have an inherent ordering. Ideally, when importing Seaborn, the default color cycle is changed to a set of six colors that evoke the standard matplotlib color cycle. But when we have more than 6, say 8 categories in our data to distinguish, then the most common way is using **hls** color space, which is a simple transformation of RGB values.

Then there is also hls\_palette() function that lets you control the lightness and saturation of colors.

All of it displayed above is just the basic Seaborn aesthetics. Let us now look at xkcd\_rgb dictionary that has 954 colors in it. Let us try to pull a few out of it:

Other style is **cubehelix** color palette that makes sequential palettes with a linear increase ordecrease in brightness and some variation in **hue**. Actually let us plot this color palette in a Density contour plot:

```
# Default Matplotlib Cubehelix version:
sns.palplot(sns.color_palette("cubehelix", 8))
```

# Default Seaborn Cubehelix version:
sns.palplot(sns.cubehelix\_palette(8))

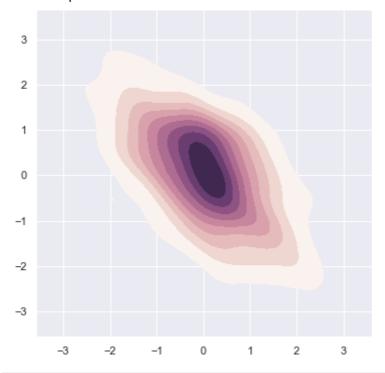

```
# Density Plot with Seaborn defaults:
x, y = np.random.multivariate_normal([0, 0], [[1, -.5], [-.5, 1]], size=300).T
sample_cmap = sns.cubehelix_palette(light=1, as_cmap=True)
sns.kdeplot(x, y, cmap=sample_cmap, shade=True)
```

SeabornColor20201ISE0024.ipynb

C:\ProgramData\Anaconda3\lib\site-packages\seaborn\\_decorators.py:36: FutureWarning:
 warnings.warn(

<AxesSubplot:>

# ☐ Interactive widget to create a sequential cubehelix palette:

Let us now play with the parameters to have some fun and choose best parameters:

sns.choose\_cubehelix\_palette(as\_cmap=True)

NameError

Traceback (most recent call last)

<ipython-input-1-230a1c9055e9> in <cell line: 1>()

----> 1 sns.choose\_cubehelix\_palette(as\_cmap=True)

NameError: name 'sns' is not defined

Note that this app only works in this Jupyter Notebook as of now to help choose best parameters for our plot:

sns.palplot(sns.cubehelix\_palette(n\_colors=8, start=1.7, rot=0.2, dark=0, light=.95, reverse=Tru

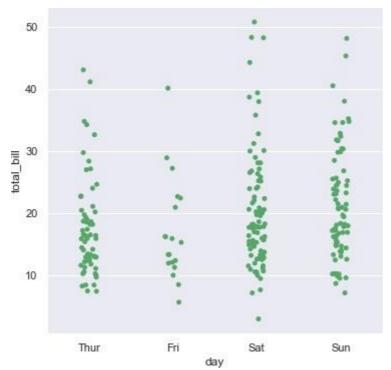

SeabornColor20201ISE0024.ipynb

start is always between 0 and 3. rot an abbreviation for rotation is kept between -1 and 1. reverse converses the color ordering and hue refers to plot appearance.

## ☐ Generic Seaborn Plots:

```
# Loading up built-in dataset:
tips = sns.load_dataset("tips")

# Creating Strip plot for day-wise revenue:
sns.stripplot(x="day", y="total_bill", data=tips, color="g")
```

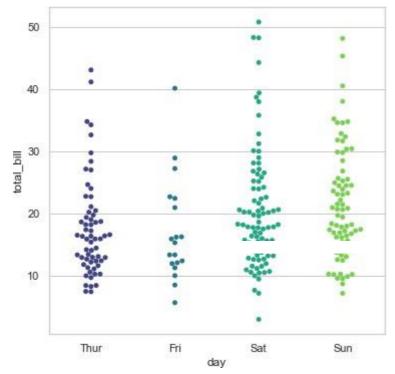

This does the job for us but let us try to get better results by plotting each day in different colorinstead of same color. For this, we shall replace **color** parameter with **palette** parameter:

```
# Set Theme:
sns.set_style('whitegrid')

# Creating Strip plot for day-wise revenue:
sns.swarmplot(x="day", y="total_bill", data=tips, palette="viridis")
```

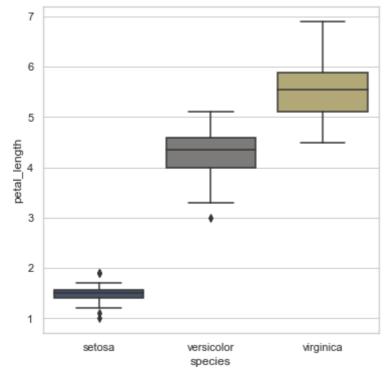

<AxesSubplot:xlabel='day', ylabel='total\_bill'>

Similarly, let us plot one more and for a change, this time we shall plot a Violin plot:

iris = sns.load\_dataset("iris")
sns.boxplot(x="species", y="petal\_length", data=iris, palette="cividis")

There are multiple such palette available for us to play around with like magma, warm grey, gunmetal, dusky blue, cool blue, deep teal, viridian, twilight blue and many more. For customized

5/15/24, 3:52 PM

SeabornColor20201ISE0024.ipynb color brewing, we may also use color brewer that also offers interesting color palettes for working with Qualitative data. The cool thing about it is that you can use the an interactive Ipython widget function to make the selection of the palette. For this, you only need to use choose\_colorbrewer\_palette().

There are multiple such palette available for us to play around with like magma, warm grey, gunmetal, dusky blue, cool blue, deep teal, viridian, twilight blue and many more. For customized color brewing, we may also use color brewer that also offers interesting color palettes for working with Qualitative data. A nice feature of the **Color Brewer website** is that it provides someguidance on which palettes are color blind safe.

The cool thing about it is that you can use the an interactive Ipython widget function to make theselection of the palette. For this, you only need to use **choose\_colorbrewer\_palette()** . To access this on your web browser, please access **ColorBrewer** link provided in the notebook.

I also found a nice representation of Color Schemes in Seaborn, that I found somewhere on web, so thought of sharing it in your Resource bucket to check out if you wish to. Let's have a look at it

### LABSHEET 11

#Installation #pip install seaborn

□ Seaborn2

## Figure

It refers to the whole figure that you see. It is possible to have multiple sub-plots (Axes) in the same figure.

#### Axes

An Axes refers to the actual plot in the figure. A figure can have multiple Axes but a given Axes can be part of only one figure.

#### Axis

An Axis refers to an actual axis (x-axis/y-axis) in a specific plot.

Four sub-plots (Axes) in a single figure.

### Seaborn

Seaborn - can create complicated plot types from Pandas data with relatively simple commands Plotting in

seaborn is either: Axes-level functions OR Figure-level function

### PLOT CATEGORIES IN SEABORN

- I. Relational plots: This plot is used to understand the relation between two variables.
- $II. \textbf{Categorical plots:} \ This \ plot \ deals \ with \ categorical \ variables \ and \ how \ they \ can \ be \ visualized.$
- $\textbf{III.} \textbf{\textbf{Distribution plots:}} \ This \ plot \ is \ used \ for \ examining \ univariate \ and \ bivariate \ distributions$
- IV. Matrix plots: A matrix plot is an array of scatterplots.
- V. **Regression plots:** The regression plots in seaborn are primarily intended to add a visual guide that helps to emphasize patterns in a datasetduring exploratory data analyses.

#Import necessary Packages import numpy as np import pandas as pd import matplotlib.pyplot as plt from matplotlib.pyplot import figure

■ Text

Code

## □ LABSHEET 12

#### Load the Pacakges

To get started, open a Colab notebook and load the Pandas, Matplotlib, and Wordcloud packages.

import pandas as pd
import matplotlib.pyplot as plt
from wordcloud import WordCloud
from wordcloud import STOPWORDS

Mount the drive and read the CSV file from the drive.

Here we are going to use netflix\_titles.csv dataset downloaded from kaggle.Since it

is text visualization we are going to consider only one column.

from google.colab import drive

drive.mount('/content/drive/')

→ Mounted at /content/drive/

df=pd.read\_csv('/content/drive/My Drive/Data/netflix\_titles.csv', usecols=['cast'])
df.head()

- 1 Ama Qamata, Khosi Ngema, Gail Mabalane, Thaban...
- Sami Bouajila, Tracy Gotoas, Samuel Jouy, Nabi...
- 3 NaN
- 4 Mayur More, Jitendra Kumar, Ranjan Raj, Alam K...

Perform Prepeocessing to remove the records containing NaN

ndf=df.dropna()
ndf.head()

cast

1 Ama Qamata, Khosi Ngema, Gail Mabalane, Thaban...

- 2 Sami Bouajila, Tracy Gotoas, Samuel Jouy, Nabi...
- 4 Mayur More, Jitendra Kumar, Ranjan Raj, Alam K...
- 5 Kate Siegel, Zach Gilford, Hamish Linklater, H...
- 6 Vanessa Hudgens, Kimiko Glenn, James Marsden, ...

The wordcloud package requires single string instead of column.

Joining the all text data of the coloumn 'cast' to single string to make text visualization easy

text = " ".join(item for item in ndf['cast'])
print(text)

Ama Qamata, Khosi Ngema, Gail Mabalane, Thabang Molaba, Dillon Windvogel, Natasha Thahane, Arno Greeff, Xolile Tshabalala, Getmore

Sometimes, there will be words in your dataframe that are insignificant and don't add any insight. We can take these out using the STOPWORDS module which is included in Wordcloud.

stopwords = set(STOPWORDS)

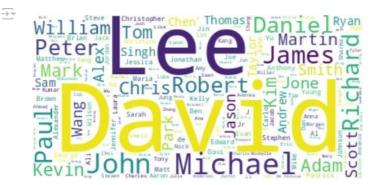

Create a basic word cloud

#### TextVisualization.ipynb - Colab

By instantiating WordCloud and then appending generate(text), we can pass in our big list of words and WordCloud will calculate the wordfrequencies, and determine the sizes, and colours of each of the words shown based on their frequencies within the text.

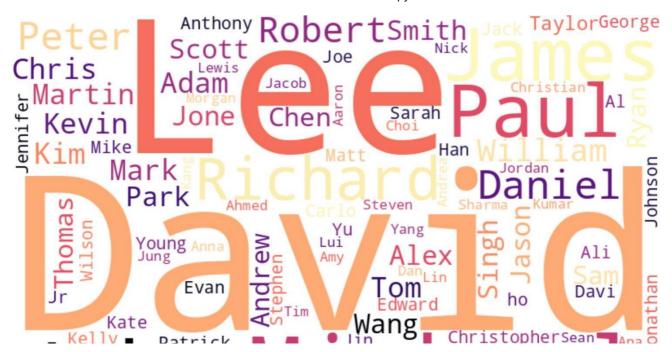

The other bits of Matplotlib code turn off the axes and ticks to make the word cloud look a bit neater.

```
wordcloud = WordCloud(background_color="white").generate(text)
plt.imshow(wordcloud, interpolation='bilinear')
plt.axis("off")
plt.margins(x=0, y=0)
plt.show()
```

#### wordcloud = WordCloud(background color="white",

## □ LABSHEET 13

A time series is the series of data points listed in time order.

A time series is a sequence of successive equal interval points in time.

A time-series analysis consists of methods for analyzing time series data in order to extract meaningful insights and other useful characteristics of data.

For performing time series analysis download stock\_data.csv

#### import pandas as pd

import numpy as np

import matplotlib.pyplot as plt

# reading the dataset using read\_csv
df = pd.read\_csv(r"stock\_data.csv")
# displaying the first five rows of dataset
df head()

$\overline{\supseteq}_{}^{\Psi}$		Date	0pen	High	Low	Close	Volume	Name
	0	1/3/2006	39.69	41.22	38.79	40.91	24232729	AABA
	1	1/4/2006	41.22	41.90	40.77	40.97	20553479	AABA
	2	1/5/2006	40.93	41.73	40.85	41.53	12829610	AABA
	3	1/6/2006	42.88	43.57	42.80	43.21	29422828	AABA
	4	1/9/2006	43.10	43.66	42.82	43.42	16268338	AABA

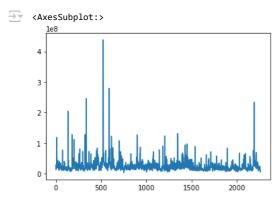

We have used the 'parse\_dates' parameter in the read\_csv function to convert the 'Date' column to the DatetimeIndex format.By default,

Dates are stored in string format which is not the right format for time series data analysis.

Now, removing the unwanted columns from dataframe i.e. 'Unnamed: 0'.

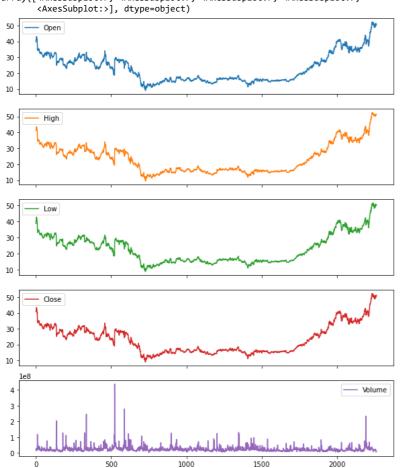

Example 1: Plotting a simple line plot for time series data.

### df['Volume'].plot()

Example 2: Now let's plot all other columns using subplot.

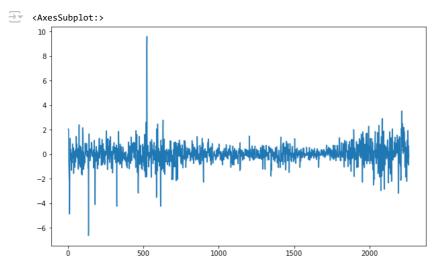

Resampling: Resampling is a methodology of economically using a data sample to improve the accuracy and quantify the uncertainty of apopulation parameter. Resampling for months or weeks and making bar plots is another very simple and widely used method of finding seasonality. Here we are going to make a bar plot of month data for 2016 and 2017.

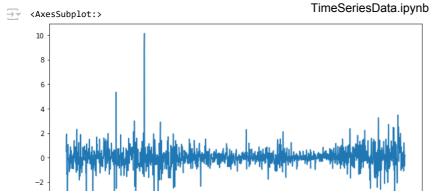

#### Example 3:

Differencing: Differencing is used to make the difference in values of a specified interval. By default, it's one, we can specify different values forplots. It is the most popular method to remove trends in the data.

df.Low.diff(2).plot(figsize=(10, 6))

df.High.diff(2).plot(figsize=(10, 6))

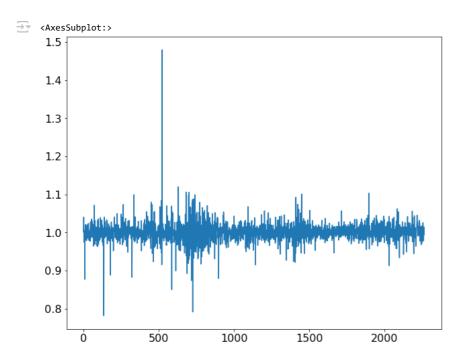

#### Plotting the Changes in Data

We can also plot the changes that occurred in data over time. There are a few ways to plot changes in data.

Shift: The shift function can be used to shift the data before or after the specified time interval. We can specify the time, and it will shift the data by one day by default. That means we will get the previous day's data. It is helpful to see previous day data and today's data simultaneously sideby side.

```
df['Change'] = df.Close.div(df.Close.shift())
df['Change'].plot(figsize=(10, 8), fontsize=16)
```

.div() function helps to fill up the missing data values.

Actually, div() means division.

If we take df. div(6) it will divide each element in df by 6.

We do this to avoid the null or missing values that are created by the 'shift()' operation. Double-
